

We need to build a scalable backend system for our application that will handle all core operations, user management, and AI integrations.

The backend will be developed using a modern stack (Node.js with TypeScript, PostgreSQL database, and Redis for performance optimization). It will be structured as a modular system so we can expand easily as the product grows.

Key components of the backend will include:

- Authentication system (login, registration, roles, security)
- User management and admin controls
- Core application logic (handling all main features of the platform)
- File handling and storage
- API layer to connect frontend, mobile app, and AI services
- Integration with AI models (Ollama / LLMs for intelligent search and responses)
- Background processing for tasks like notifications and data handling

The system will be designed to support:

- Scalable deployment on cloud servers
- High-performance search (including AI-based similarity search)
- Secure and structured data management
- Future expansion into additional services and integrations

The goal is to first build it as a strong, modular backend (monolithic architecture), and later scale into microservices if needed.
