

# sellsell marketplace updates - 10042026

UPDATE: 10/04/2026:12:27AM

SHAZ EJ

The Marketplace Ranking Intelligence architecture has been fully executed. No additional database queries were required—it all runs lightning fast in-memory over Qdrant's raw result pool.

How I implemented it:

1. Dynamic Intent Regex: I added deterministic regex parsing directly into the pre-processor (`parseFiltersFromText`) to flawlessly identify what the user cares about most (e.g., `"cheapest" -> price`, `"rolex/brand new" -> quality`, `"today" -> freshness`). You can see this intent directly represented in the `SearchCriteria` payload.
2. Broad Fetching: Qdrant now always fetches `limit 5` (typically 50 results) to cast a wide semantic net.
3. In-Memory Median Baseline: Since querying SQL for market medians is slow, the engine now calculates the median price of those highly-relevant 50 fetched items on the fly. This serves as our "Category Baseline".
4. The Math Engine:
  - Qdrant's cosine scores are normalized `0.0 -> 1.0`.
  - A recency curve penalizes old listings.
  - `Price Value` pushes listings below the median toward `1.0`.
  - A clean `Quality Trust` additive score spots multi-photo, verified-seller listings.
5. Score Fusion: The `userPriority` intent drastically shifts the weights exactly how we specified in the artifact.

When you search for `"cheap family car"`, a highly relevant but expensive car will now cleanly lose to an average-relevance, insanely-well-priced car. The "Best Match" badge up top will logically point to exactly what the user is really searching for.

Are there any other priorities before we consider this buying flow mathematically bulletproof and aesthetically locked?
